

Deciphering Everyday Hidden Hearing Loss Using Statistical and Machine Learning Methods

Zhou Long,

Grade 11, Westmount Charter School

Supervised by Dr. Jun Yan (MD, Professor), University of Calgary

Background

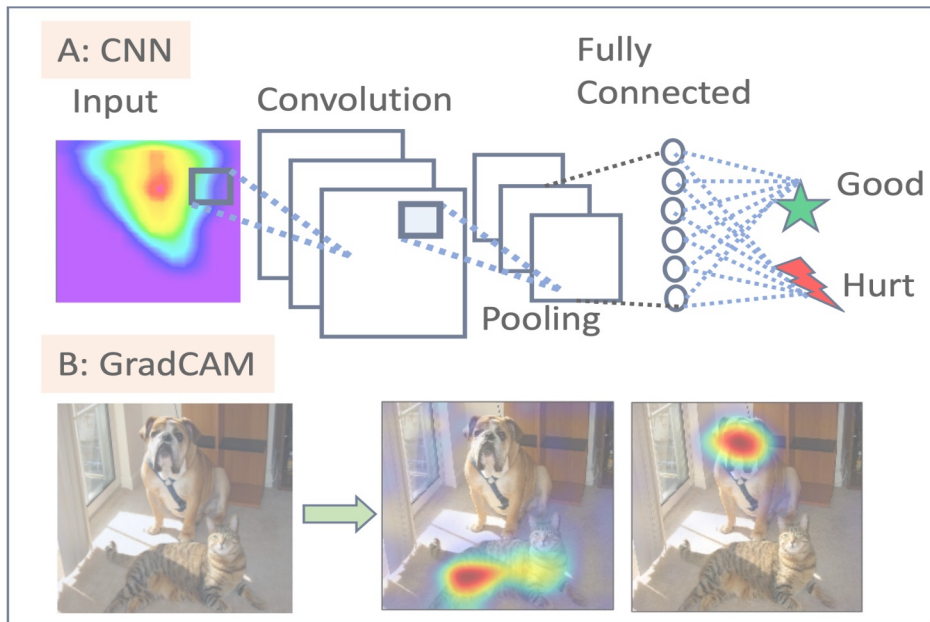

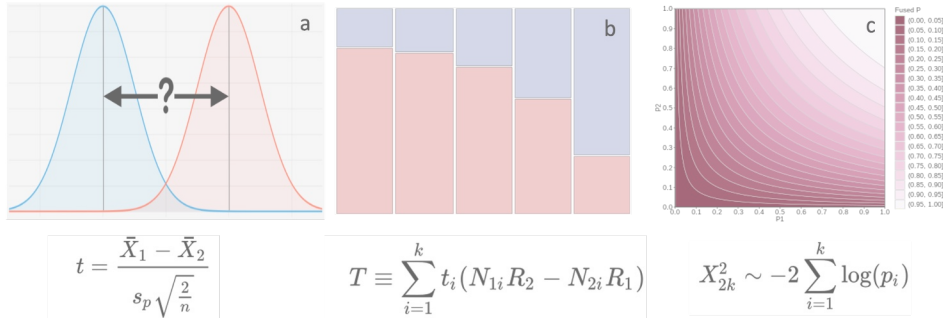

- More than 1.5 Billion people, or 20% of the global population suffer from hearing loss (WHO). This number is expected to increase to over 2.5 Billion by 2050.
- Between 12% and 15% of these cases are caused by hidden hearing loss. That is over 200 million people.
- Hidden hearing loss not assessable by conventional hearing tests.
- Additionally, it is especially dangerous due to possible damage from “safe” sounds.
- Damage occurs in the form of atypical neuronal activities in the auditory system of the brain.

Question: How can we quantify and detect hidden hearing loss?

Pictures from the internet

Aims of the Project

1. Using rigorous statistical tests (upper panel) to **reveal** that hidden hearing loss exists in the form of atypical neuronal response.
2. Using machine learning techniques (lower panel) to **detect** hidden hearing loss and decipher the **specific spectrum** of amplitude and frequency for a clinical diagnostics.

Contributions:

- The experimental data was collected by Ms. Wenyue Xue (a PhD student in Dr. Jun Yan's group).
- My contributions are the statistical and computational works achieving the two Aims. Code and Software for the analysis are in my GitHub: https://github.com/ZhouLongCoding/sound_waves

Methods (1.1): Experiments & Data processing

Mouse experiments

- A mouse is fixed on the bench, exposing to a pre-specified pure-tone sound.
- Pre- and post- the responses of auditory midbrain neurons to sound stimuli are recorded by a specific equipment and assessed via conventional methods.
- An enlarged view of the animal experiment scenario

Data Processing

- Conversion from binary to texts
- Smoothing the data

In total, the input data configuration:

- 18 mice are experimented.
- 36 Amplitudes 21 frequencies, at 100 time points are assessed for each mice at 2 conditions (pre- and post-)
- Total number of the data points = 2,721,600

Methods (1.2): Feature Extraction for Statistical Tests

The **Raw data** after processing are depicted 4D data (Neuronal Firing Rate with respect to three dimensions: **Frequency**, **Amplitude**, **Time**) in the **Upper panel**. Different **Time** points are shown in **a – h**. In each sub-panel **Frequency** is shown in x-axis, and **Amplitude** is shown in y-axis, the colour indicates strength of the **neuronal firing rate**.

Feature extractions are conducted (**Lower pane**):

Frequency domain (fixing both Amplitude and Time)

- **Best frequency**, the Frequency with the highest firing rate (**Lower panel a**);
- **Bandwidth**, the frequency range that has firing-rate substantially differ from zero (**Lower panel b**)

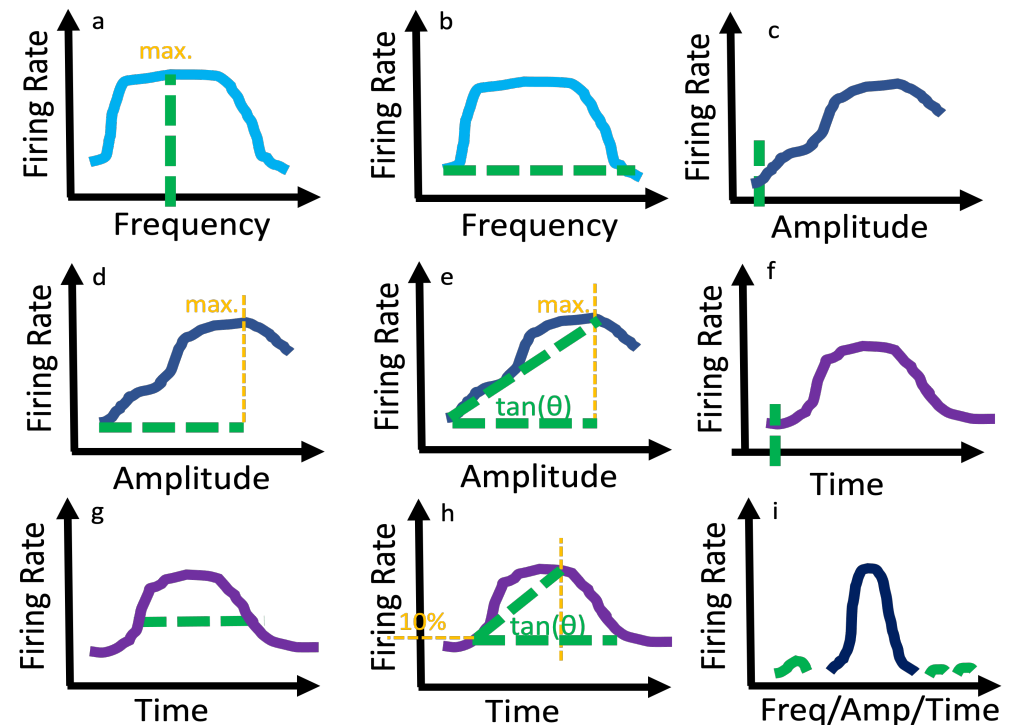

Amplitude domain (fixing both Frequency and Time)

- **Threshold**, the lowest response amplitude (**Lower panel c**);
- **Dynamic range**, the amplitude difference between lowest firing-rate and the turn point (after which the increase of firing-rate slows down), which is approximately maximal the second derivative of the firing rate curve (**Lower panel d**);
- **Slope of dynamic range**, the distance in firing rate divided by the dynamic range described above (**Lower panel e**).

Time domain (fixing both Frequency and Amplitude)

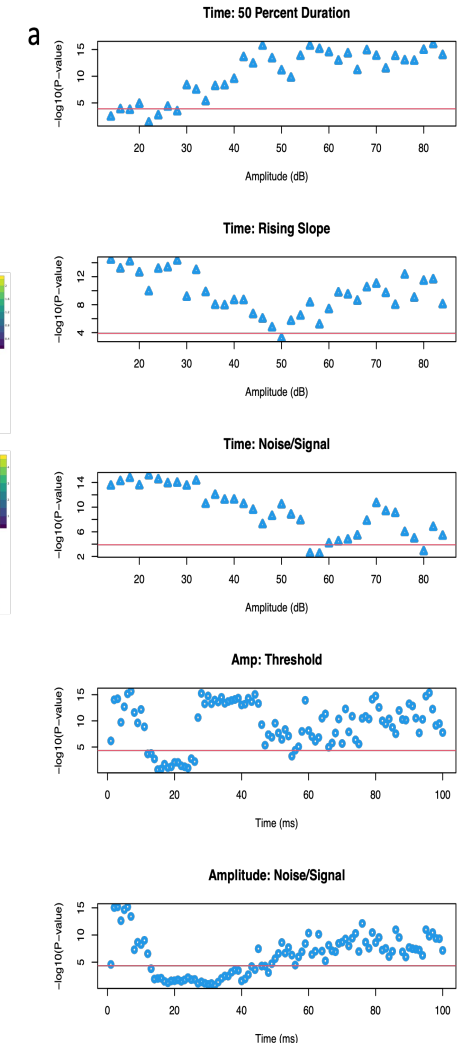

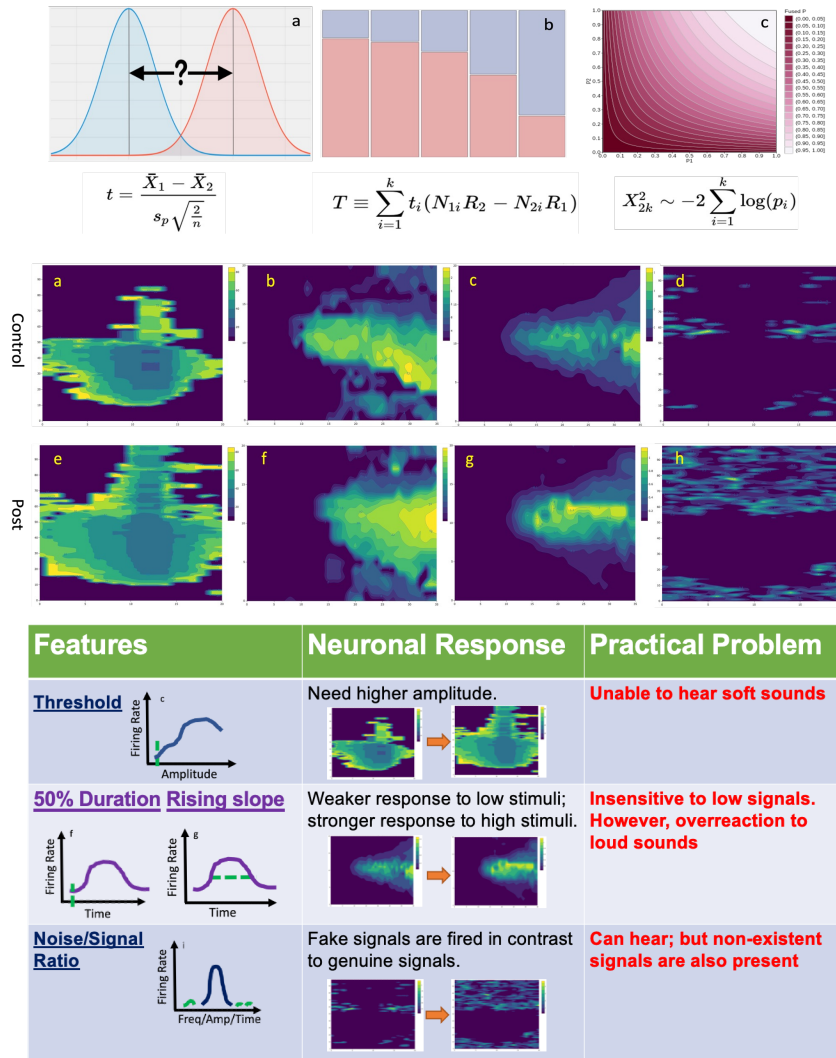

- **Latency**, the time point when a response starts (**Lower panel f**);
- **50% Duration**, the period when firing rate is over 50% of the maximum firing-rate of each response (**Lower panel g**);
- **Rising slope**, the slope from the 10% of the maximum firing-rate to the maximum firing-rate (**Lower panel h**).

Noise/Signal Ratio to ((**Lower panel i**) for **all the three domains**.

Results 1: Hidden hearing loss exists! (Statistical Tests + Interpretations)

- T-test and Trend-test (**Upper-left panel, a and b**) are used to assess the significant level of effects. Fisher method (**Upper-left panel, c**) is used to combine multiple mice experiments (Pictures illustrating tests from internet)
- Significance level in T-tests (**Right panel**) for five features.
- The above features are illustrated as contour graphs (**Mid-left panel, a-d**: pre-exposure; **e-h**: post exposure; **a,e**: Amplitude Threshold; **b,f**: Time 50 duration; **c,g**: Time rising slope; **d,h**: Amplitude Noise/Signal ratio)
- The illustrated features are annotated using physiological interpretations (**Lower-left panel, a – c**) (Interpretation provided by Dr. Jun Yan)

Methods (Aim 2): Identifying specific spectrums for clinical tests

Goal:

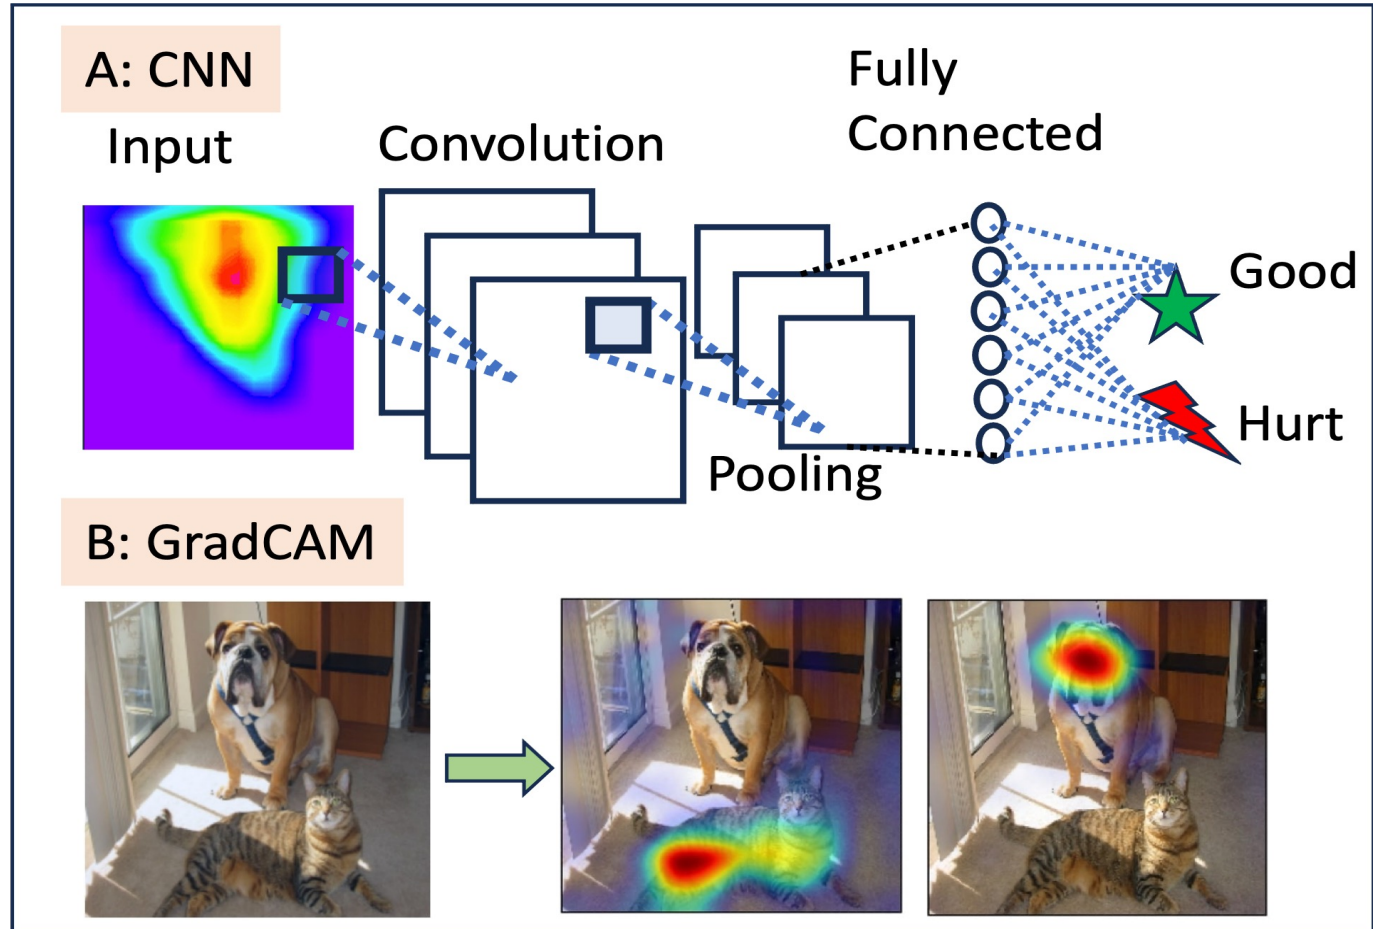

- Detect and identify specific amplitude and frequency that best distinguish pre-exposure and -post exposure.

The analytic pipeline:

- **Convolutional neural network** is used to train a classifier distinguishing pre- and post-exposure using input data as images. This allows detection of hidden hearing loss, which has been previously impossible.
- **eXplainable AI** (particularly **GradCAM**) is used to identify the spectrums (amplitude and frequency) that best distinguish pre- and post exposures.

Overfitting control:

- De-noising the input data
- Cross-Validation
- Early stopping

Cat/Dog image from the GradCAM paper: Selvaraju *et al.*, ICCV 2017

Hyper-parameters & Training for Convolutional Neural Network

Network configurations:

- Kernel size = (3, 3)
- Pool size = (2,2)
- Dense layer number of nodes = 128
- Number of layers = 3

Training parameters:

- Epochs = 20
- Batch Size = 12
- Optimizer = 'adam'
- Learning rate = 0.001
- Kernel initializer = HeNormal()

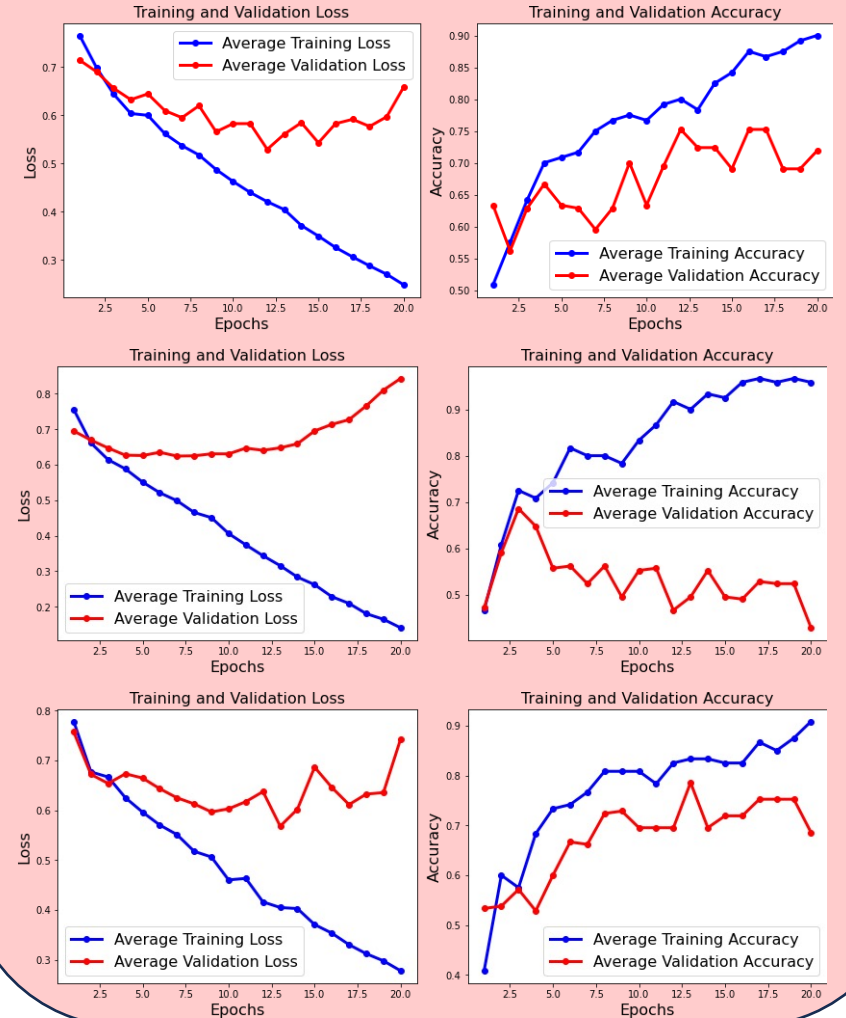

Data processing:

- De-noise: Median filter
- Mean normalization:
 - $X' = (X - \text{mean}(X)) / (\text{max}(X) - \text{min}(X))$

Model summary

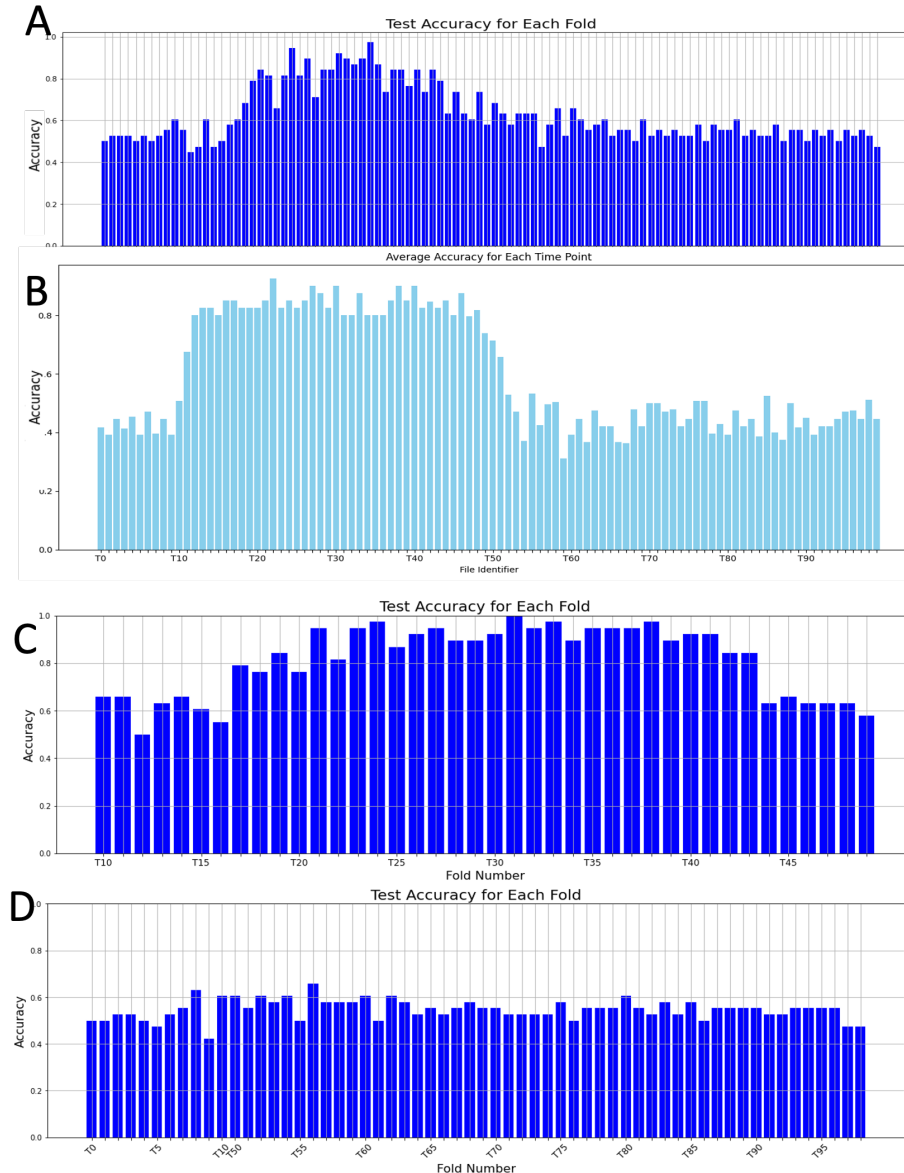

| Layer (type) | Output Shape | Param # |
|--------------------------------------|--------------------|---------|
| conv1 (Conv2D) | (None, 33, 19, 32) | 320 |
| MaxPooling1 (MaxPooling2D) | (None, 16, 9, 32) | 0 |
| conv2 (Conv2D) | (None, 14, 7, 64) | 18496 |

| Output (Dense) | (None, 2) | 258 |
| ----- | | |
| Total params: 174978 (683.51 KB) | | |
| Trainable params: 174978 (683.51 KB) | | |
| Non-trainable params: 0 (0.00 Byte) | | |

Loss & Accuracy graphs:

Predictive Accuracy & Overfitting Control

- Data in Time point 0-9 and 50-99 are known (biologically) to be noisy.
- I used this prior knowledge to analyze potential overfitting in the training process and select the best model
- First, when trains all data jointly, the accuracy in the range of T=10 to T=49 indeed are better (**Panel A**).
- Second, when trained individually, the advantage of T=10 to T=49 are more pronounced (**Panel B**).
- Third, when analyzing the data jointly for T=10 to T=49 (**Panel C**) and T=0 to T=9 and T=50 to T=99 (**Panel D**), the performance of T=10 to T=49 are way better, replicating the patterns observed in **Panels A** and **B**.
- The above observation shows that the model is no overfitting (because of the poor data serve as controls) and we should use only T=10 to T=49 for further discoveries.

Results 2: eXplainable AI (GradCAM) reveals the final spectrum

GradCAM generates weights specifying importance of each spots on the image, which are aggregated to lead the final outcome:

For a potential clinic test, The best range and spectrum is **Amp = 46-70 dB**, **Freq = 8.7-13.2 KHz** (with respect to the specific exposure)

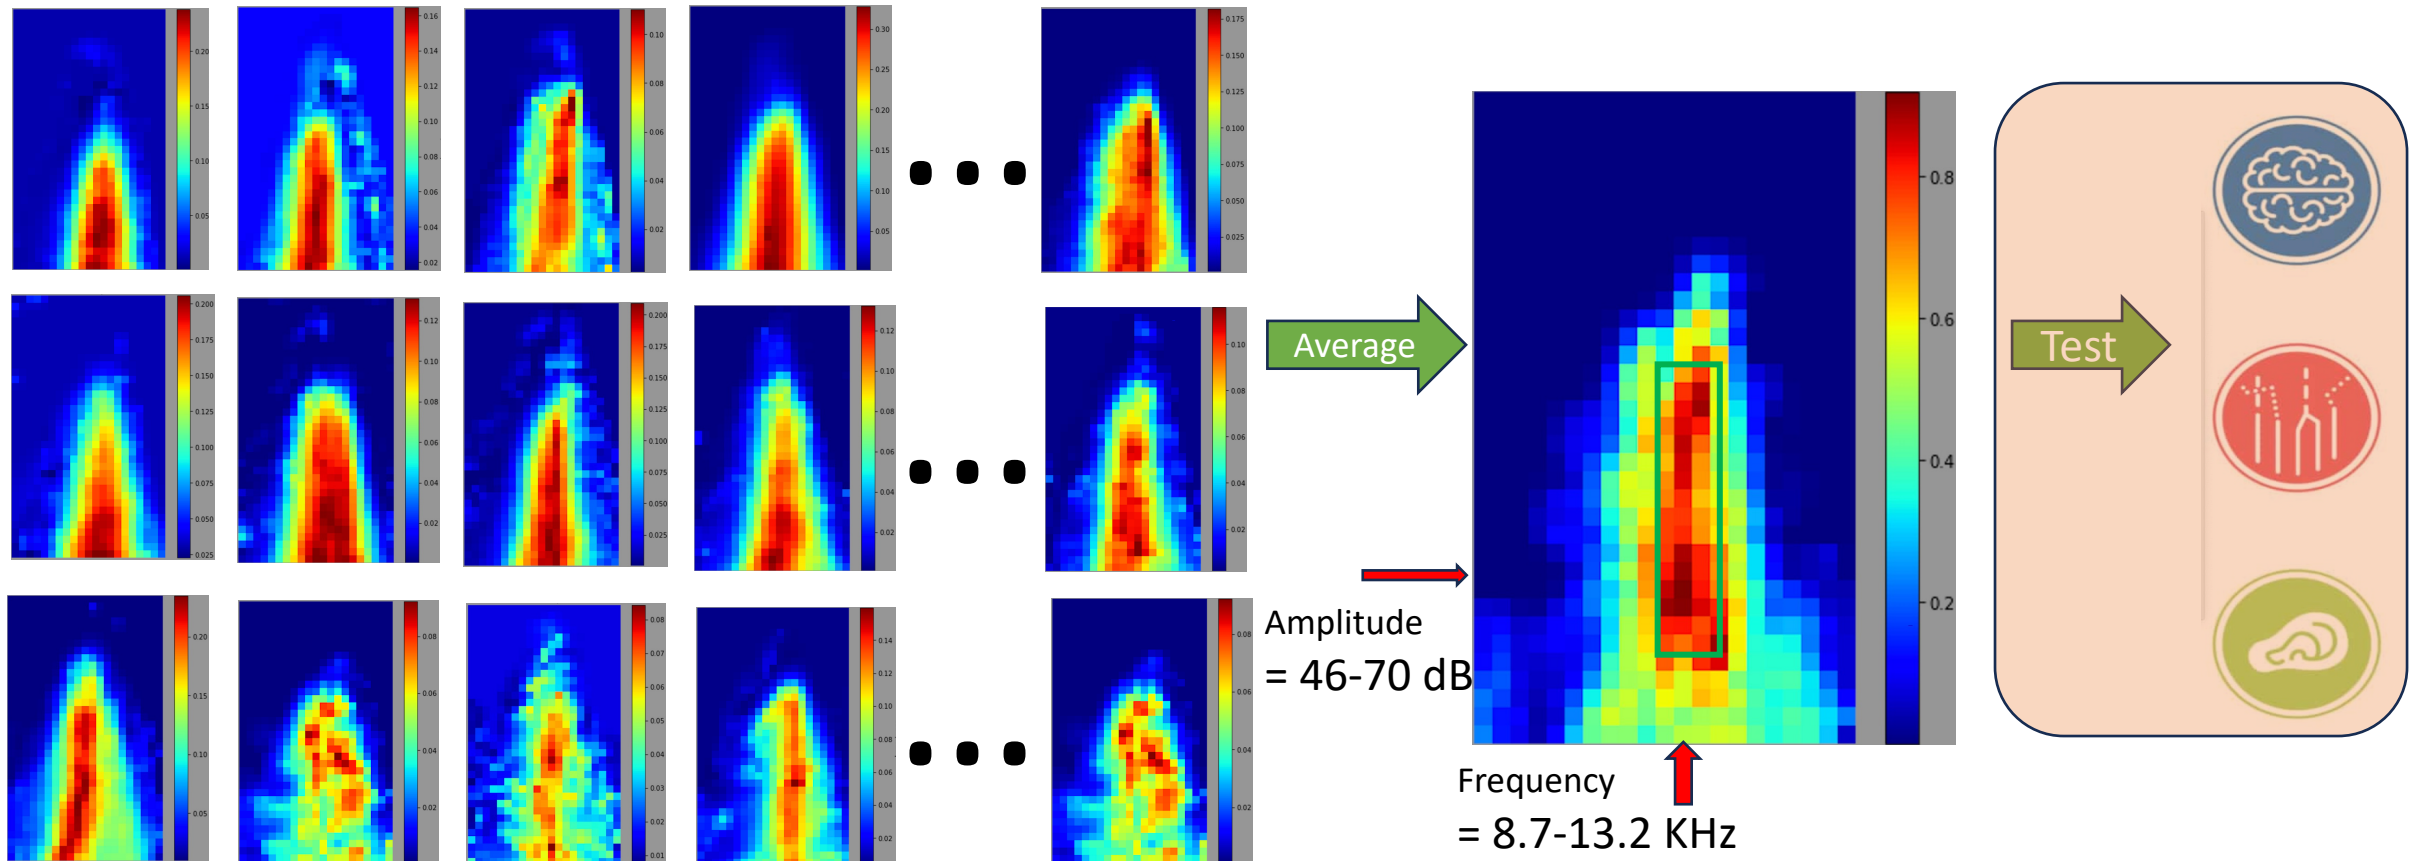

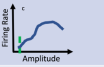

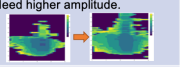

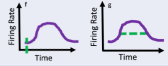

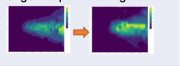

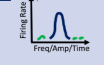

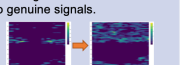

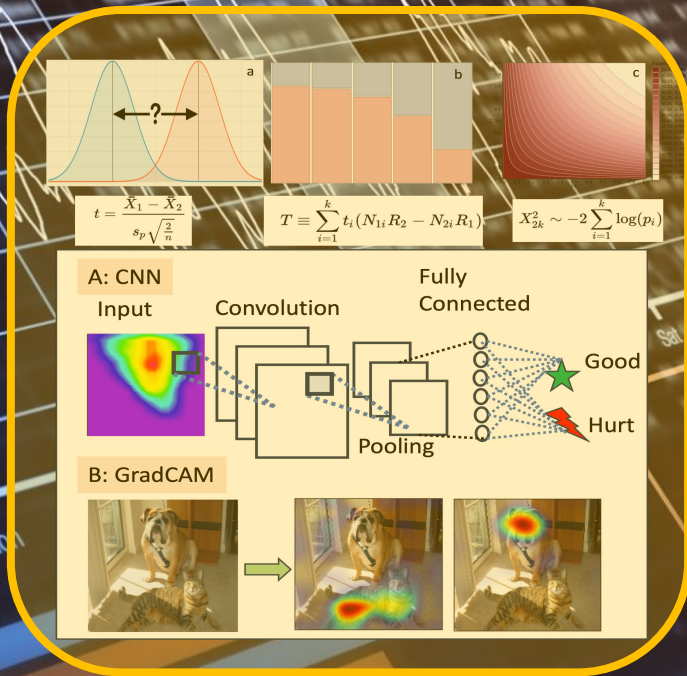

Image indicating clinical test from American Academy of Audiology

| Features | Neuronal Response | Practical Problem |
|---|---|---|
| Threshold  | Need higher amplitude.  | Unable to hear soft sounds |
| 50% Duration Rising slope  | Weaker response to low stimuli; stronger response to high stimuli.  | Insensitive to low signals. However, overreaction to loud sounds |
| Noise/Signal Ratio  | Fake signals are fired in contrast to genuine signals.  | Can hear; but non-existent signals are also present |

Conclusion and Take Home Message

- Hidden hearing loss is significant and can be caused by safe sounds, shown by the statistical tests (Results 1)
- Trained a convolutional neural network to **detect** hidden hearing loss exists in a sample.
- Identified the specific range of **Amplitude/Frequency** that is the most informative in distinguishing pre- and post-exposure, laying the path for clinical tests. (Results 2)
